Linear Algebra

Matrix multiplication

If A is a $n \times m$ matrix and B is a $m \times k$ matrix then the matrix AB of dim $n \times k$ is defined by:

$$[AB]_{xy} = \sum_{\text{all}(z)} A_{xz} B_{zy}$$

Inner Product

The inner product (dot product) of 2 vectors \vec{a}, \vec{b} in \mathbb{R}^n is defined as

$$\vec{a} \cdot \vec{b} = \langle \vec{a}, \vec{b} \rangle = \sum_{k=1}^n a_k b_k$$

Eigenvalues and Eigenvectors

We can find eigenvalues by solving for the roots of the characteristic polynomial of the matrix \mathbf{A} .

$$\det(\mathbf{A} - tI_n) = 0$$

Where I_n is the $n \times n$ identity matrix. Then for each eigenvalue $t = c$ we can solve the system of linear equations

$$(\mathbf{A} - cI_n)\vec{x} = \vec{0}$$

\vec{x} will be an eigenvector of \mathbf{A} .

Assignment Theorems

$$\mathbb{E}[Xf(Y)] = \mathbb{E}[f(Y) \cdot \mathbb{E}(X \mid Y)] \quad (\text{hw1q6})$$

1 Week 1

1.1 Definition (Stochastic Process). Let $(X_t)_{t \in T}$ be a collection of random variables this is called a Stochastic Process. T is the *index set*.

1.2 Example (Simple Random Walk on \mathbb{Z}). Let $X_i \sim \text{iid}$ where $X_i \in \{-1, 1\}$ with

$$P(X_i = 1) = \frac{1}{2}$$

$$P(X_i = -1) = \frac{1}{2}$$

now let

$$S_n = \sum_{i=0}^n X_i$$

Then $(S_i)_{i=0}^\infty$ is a stochastic process.

1.3 Definition (Transition Probability). Given $(X_s)_{s \leq t}$ we need the probability for X_{t+1} .

$$P(X_{(t+1)} = x_{t+1} | X_1 = x_1, X_2 = x_2, \dots, X_t = x_t)$$

1.4 Note. Conditional Probability Properties

$$P(A|B) = \frac{P(AB)}{P(B)} \quad P(B) > 0$$

$$P(ABC) = P(A|BC) \cdot P(B|C) \cdot P(C)$$

1.5 Example. Transition Probabilities for SRW on \mathbb{Z}^d

$$P(\|X_{t+1} - X_t\| = 1 \mid (X_s)_{s \leq t}) = \frac{1}{2d}$$

1.1 Markov Chains

1.6 Definition (Markov Property). A process has the Markov property if:

$$P(X_{t+1} = x_{t+1} \mid (X_s)_{s \leq t}) = P(X_{t+1} = x_{t+1} \mid X_t = x_t)$$

(Next outcome only depends on the previous outcome)

1.7 Note (Markov Chain). A stochastic process that satisfies the [Markov property](#) is called a Markov chain.

1.8 Definition (Time Homogeneous Markov Chain). A Markov Chain is called time homogeneous if the following is true

$$P(X_{t+1} = j \mid X_t = i) = P(X_1 = j \mid X_0 = i)$$

1.9 Definition (Stochastic Matrix). A matrix \mathbf{P} is called stochastic if

$$\mathbf{P} = \begin{pmatrix} p_{00} & p_{01} & \cdots \\ p_{10} & p_{11} & \cdots \\ \vdots & \ddots & \end{pmatrix}$$

$$0 \leq p_{ij} \leq 1$$

$$\sum_{all(j)} p_{i_0j} = 1 \text{ for fixed } i_0$$

1.10 Definition (Transition Matrix). Let \mathbf{P} be a [Stochastic matrix](#) and let p_{ij} = value in i -th row and j -th column. We define p_{ij} as

$$p_{ij} = P(X_t = j \mid X_{t-1} = i)$$

(probability of going from state i to state j in the chain).
This is called the transition matrix for $(X_t)_{t \in T}$.

1.11 Example. Transition Matrix Consider this transition matrix The transition matrix for this Markov Chain is

$$\begin{array}{c} 1 \quad 2 \quad 3 \\ \begin{array}{c} 1 \\ 2 \\ 3 \end{array} \begin{pmatrix} 0 & \frac{1}{2} & \frac{1}{2} \\ \frac{1}{3} & 0 & \frac{2}{3} \\ \frac{1}{3} & \frac{2}{3} & 0 \end{pmatrix} \end{array}$$

this can be visualized as:

1.1.1 Multistep Transition Probabilities

1.12 Definition.

$$[P(n, n+m)]_{xy} = P(X_{n+m} = y \mid X_n = x)$$

1.13 Theorem. Multistep Transition Probability Matrix Let $(X_t)_{t \in T}$ be a stochastic process satisfying the Markov property and be *time homogeneous* and let \mathbf{P} be the transition matrix.

$$[P(n, n+m)]_{xy} = \mathbf{P}_{xy}^m$$

1.14 Lemma.

$$[P(n, m+1+n)]_{xy} = \sum_{\text{all}(z)} [P(n, m+n)]_{xz} P_{zy}$$

Proof. To go from state $x \rightarrow y$ we must add up all probabilities of going to an intermediate state z , $x \rightarrow z \rightarrow y$ we add possibilities of z .

$$\begin{aligned} [P(n, m+1+n)]_{xy} &= P(X_{m+1+n} = y \mid X_n = x) \\ &= \sum_{\text{all}(z)} P(X_{m+1+n} = y, X_{n+m} = z \mid X_n = x) \text{ Marginal probability function (stat240)} \\ &= \sum_{\text{all}(z)} P(X_{m+1+n} = y \mid X_{n+m} = z, X_n = x) P(X_{n+m} = z \mid X_n = x) \text{ conditional probability} \end{aligned}$$

Since X_t satisfies the Markov property we get

$$= \sum_{\text{all}(z)} P(X_{m+1+n} = y \mid X_{n+m} = z) P(X_{n+m} = z \mid X_n = x)$$

By definition we have $P(X_{m+1+n} = y \mid X_{n+m} = z) = P_{zy}$ and $P(X_{n+m} = z \mid X_n = x) = [P(n, n+m)]_{xz}$. \square

Using [Lemma 1.14](#) we can prove the [Theorem 1.13](#).

Since [1.14](#)'s result is the definition of matrix multiplication we get

$$[P(n, m+1+n)]_{xy} = [P(n, m+n)P]_{xy}$$

by induction on m with base case $P(n, n+1) = P$ we get

$$[P(n, m+1+n)]_{xy} = \mathbf{P}^m$$

Since RHS does not depend on n we can write $P(n, n+m) = P(m)$ and time homogeneity applies for any m number of steps.

$$P(X_{n+m} = y \mid X_n = x) = P(X_m = y \mid X_0 = x)$$

2 Week 2

2.1 Initial Data

Let $(X_n)_{n \in I}$ be a time homogeneous Markov chain. We denote these by $0, 1, 2, \dots, |I| - 1$. We represent the state space as:

$$\{i_1, i_2, \dots, i_{|I|}\} = \mathcal{X}$$

Let \mathbf{P} be the transition matrix for this Markov chain.

2.1 Definition (Distribution Row Vector).

$$\mu_j = P(X_0 = i_j)$$

Then the row vector $\vec{\mu}$ of $\dim = 1 \times |I|$ is defined as

$$\vec{\mu} = [\mu_1, \mu_2, \dots, \mu_{|I|}]$$

$\vec{\mu}$ is called the distribution of X_0 denoted by $X_0 \sim \vec{\mu}u$.

The distribution vector for X_n is denoted by $\mu(n)$.

2.2 Theorem. Distribution of X_n The distribution row vector of X_n for a time homogeneous Markov chain is given by μP^n

Proof. Sketch.

$$P(X_n = i_k) = \sum_{j=1}^{|I|} P(X_n = i_k \mid X_0 = i_j) P(X_0 = i_j) = \sum \vec{\mu}_j P_{jk} = [\vec{\mu} P]_k$$

Implies $X_n \sim \vec{\mu} P^n$

□

2.2 Conditional Expectation

Given $f : \mathcal{X} \rightarrow \mathbb{R}$ what is the expected value of $f(X_m)$ given an initial distribution?

The function f on a finite state space \mathcal{X} is equivalent to a vector $\vec{f} \in \mathbb{R}^{|\mathcal{X}|}$

$$\vec{f} = \begin{pmatrix} f(1) \\ f(2) \\ \vdots \\ f(n) \end{pmatrix}$$

The conditional expectation for $f(X_m)$ given $X_0 \sim \vec{\mu}$ is denoted by

$$\mathbb{E}(f(X_m) \mid X_0 \sim \vec{\mu})$$

By definition of conditional expectation we get

$$\begin{aligned} \mathbb{E}(f(X_m) \mid X_0 \sim \vec{\mu}) &= \sum_{k=1}^{|\mathcal{X}|} f(i_k) P(X_m = i_k \mid X_0 \sim \vec{\mu}) \\ &= \sum_{\text{all}(k)} f(i_k) [\vec{\mu} \mathbf{P}^m]_k \\ &= \sum_{\text{all}(k)} \vec{f}_k [\vec{\mu} \mathbf{P}^m]_k \\ &= \langle \vec{\mu} \mathbf{P}^m, \vec{f} \rangle \end{aligned}$$

2.3 Stationary Distribution

Suppose $X_0 \sim \vec{\mu}$ then the distribution for $X_n \sim \vec{\mu}(n)$ then what is the limit of $\vec{\mu}(n)$ as $n \rightarrow \infty$. Suppose the limit $\lim_{n \rightarrow \infty} \vec{\mu}P^n = \vec{\pi}$ exists then we can write

$$\vec{\pi} = \lim_{n \rightarrow \infty} \vec{\mu}P^n = \lim_{n \rightarrow \infty} \vec{\mu}P^{n-1}P = \lim_{n \rightarrow \infty} \vec{\mu}(n-1)P = \vec{\pi}P$$

So $\vec{\pi}$ is an **left eigenvector** of \mathbf{P} with **eigenvalue 1**.

2.3 Definition (Stationary Distribution). A probability vector $\vec{\pi}$ is the Stationary Distribution for the stochastic matrix \mathbf{P} if

$$\begin{aligned} \sum_k \vec{\pi}_k &= 1 \\ \vec{\pi}P &= \vec{\pi} \end{aligned}$$

2.4 Definition (Stationary Measure). A measure $\vec{\nu}$ on \mathcal{X} ($\vec{\nu} \in \mathbb{R}^{|\mathcal{X}|}$) if

$$\begin{aligned} \vec{\nu}_i &\geq 0 \\ \sum \vec{\nu}_i &> 0 \\ \vec{\nu}P &= \vec{\nu} \end{aligned}$$

2.5 Proposition (Stationary Distribution from Measure). If $|\mathcal{X}| < \infty$ and $\vec{\nu}$ is a stationary measure on \mathbf{P}

$$\vec{\pi} = \frac{1}{\sum_i \vec{\nu}_i} \vec{\nu}$$

Then $\vec{\pi}$ is a stationary distribution by definition.

2.6 Definition (Bi-stochastic Matrix). A **stochastic matrix** is Bi-stochastic if

$$\sum_{\text{all}(i)} P_{ij_0} = 1 \quad \text{for fixed } j_0$$

Sum of all rows = 1 and sum of all columns = 1.

2.7 Proposition (Stationary Distribution for Bi-stochastic Matrices). If \mathbf{P} is a **Bi-stochastic** transition matrix for Markov chain with finite state space \mathcal{X} with $|\mathcal{X}| = N$ then the stationary distribution is given by

$$\vec{\pi} = \left(\frac{1}{N} \quad \frac{1}{N} \quad \cdots \quad \frac{1}{N} \right)$$

2.4 Detail Balance Condition

2.8 Definition (Detail Balance Condition). $\vec{\pi}$ has the detail balance condition if:

$$\vec{\pi}_x \mathbf{P}_{xy} = \vec{\pi}_y \mathbf{P}_{yx}$$

2.9 Note. Detail balance condition means $\mathbb{P}(X_1 = x, X_0 = y) = \mathbb{P}(X_1 = y, X_0 = x)$.

2.10 Theorem (Detail Balance and Stationary Distribution). If $X_0 \sim \vec{\pi}$ and $\vec{\pi}$ satisfies the [detail balance condition](#) then $X_n \sim \vec{\pi}$ for all $n \geq 1$

3 Week 3

3.1 Communicating States

3.1 Definition (communicating states). A state x communicates with y if $\exists n \geq 1$ such that

$$[\mathbf{P}^n]_{xy} > 0$$

denoted by $x \rightarrow y$.

3.2 Note. $\mathbb{P}(A \mid X_{n-1} = x) = \mathbb{P}_x(A)$ and $\mathbb{E}(\cdot \mid X_n = x) = \mathbb{E}_x(\cdot)$

3.3 Definition (Time of the first return / first hitting time).

$$\tau_x = \min\{n \mid X_n = x\}$$

$$\rho_{xy} = \mathbb{P}_x(\tau_y < \infty)$$

$\rho_{xy} = \mathbb{P}(X_n \text{ returns to } y \text{ given it starts at } x)$.

3.4 Note.

$$1 - \rho_{xy} = \mathbb{P}_x(\tau_y = \infty)$$

3.5 Lemma (Communicating states and return probability). $x \rightarrow y \iff \rho_{xy} > 0$.

3.6 Lemma (Transitivity). $x \rightarrow y$ and $y \rightarrow z \Rightarrow x \rightarrow z$

3.7 Definition (Time of k -th return).

$$\tau_x^k = \min\{n > \tau_x^{k-1} \mid X_n = x\}$$

where $\tau_x^1 = \tau_x$.

3.2 Recurrent and Transient States

3.8 Definition (Recurrent and Transient States). A state $x \in \mathcal{X}$ is called **recurrent** if

$$\rho_{xx} = 1$$

and **transient** if

$$\rho_{xx} < 1$$

3.9 Theorem (Escaping path). If $x \rightarrow y$ and $\rho_{xy} < 1$ then x is transient.

3.10 Theorem (Corollary of Escaping Path theorem). If $x \rightarrow y$ and x is recurrent then $\rho_{xy} = 1$.

3.3 Strong Markov Property

3.11 Definition (Stopping Time). T is a stopping time if the occurrence (or non occurrence) of the event $\{T = n\}$ can be determined by $\{X_0, \dots, X_n\}$.

3.12 Theorem (Strong Markov Property). Suppose T is a stopping time. Given $T = n$ and $X_T = y$ the random variables $\{X_{T+k}\}_{k=0}^{\infty}$ behave like a Markov chain starting from initial state y . That is

$$\mathbb{P}(X_{T+1} = z \mid X_T = y, T = n) = \mathbb{P}(X_1 = z \mid X_0 = y) = \mathbf{P}_{yz}$$

3.13 Lemma (k -th return time and the strong Markov property). Let τ_y^k be the k -th return time to y . Then the strong Markov property implies

$$\mathbb{P}_x(\tau_y^k < \infty) = \rho_{xy}\rho_{yy}^{k-1} \text{ or } \mathbb{P}_y(\tau_y^k < \infty) = \rho_{yy}^k \quad \forall k \geq 1$$

3.14 Note. From the above lemma if we have $\rho_{yy} = 1$ (y is recurrent) then the chain returns to y for infinitely many k and it continually recurs in the Markov chain.

Otherwise if $\rho_{yy} < 1$ (y is transient) then $\rho_{yy}^k \rightarrow 0$ as $k \rightarrow \infty$ so after sometime y is never visited in the chain.

4 Week 4

4.1 Classification of States

4.1 Definition (Closed). A set A is **closed** if it is impossible to get out. Formally $c \in A$ and $y \notin A$ then $P_{xy} = 0$

4.2 Definition (irreducible). A set B is irreducible if every state is reachable from another in k steps or every state communicates with all other states. Formally

$$x, y \in B \Rightarrow x \rightarrow y$$

4.3 Lemma (Commutating recurrent states). If x is **recurrent** and $x \rightarrow y$ then y is recurrent

4.4 Lemma (Existence of recurrent states in finite closed sets). If A is finite and **closed** then $\exists x \in A$ such that x is **recurrent**.

4.5 Theorem (Closed and irreducible sets are recurrent). If $C \subseteq \mathcal{X}$ is **finite**, **closed** and **irreducible** then all $x \in C$ are **recurrent**.

4.6 Theorem (Decomposition Theorem). If \mathcal{X} is finite then

$$\mathcal{X} = T \cup R_1 \cup R_2 \cup \dots \cup R_k$$

where T is the set of transient states and R_i for $1 \leq i \leq k$ are closed irreducible sets of recurrent states.

4.7 Definition (Number of visits). $N(y)$ is the number of visits to y after initial time.
